

Understanding the Architecture of a Linux System

By: Michael Ilodigwe

Linux System Components

Kernal

Shell

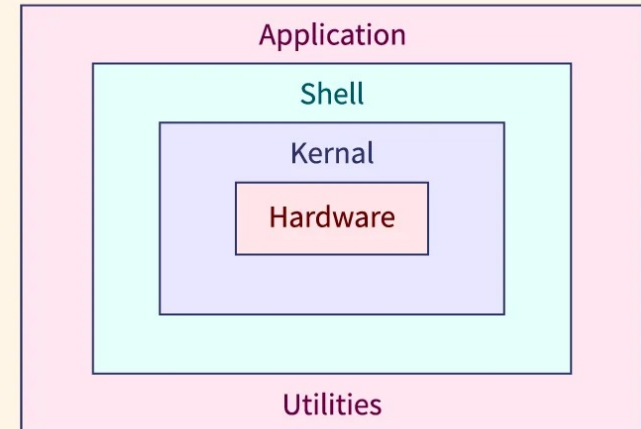

Utilities

File System

Graphical User Interface (GUI)

Architecture

Kernel

Definition: core component

Role: manages hardware resources, schedules tasks, and provides essential functionalities

Core Subsystems
of the Linux Kernel
are as follows:

The Process Scheduler
Memory Management Unit
The Virtual File System
The Networking Unit
Inter-Process
Communication Unit

Shell

Definition: Command-line interface that interprets user commands and executes them

Types: Bash (Bourne Again Shell)

Zsh (Z Shell)

Fish (Friendly Interactive Shell), etc.

Shell acts as an intermediary between users and the kernel.

Utilities

Definition: Broad range of software tools and applications that provide essential functionality for users and system administrators

Three examples of the different type of utilities:

System Management (``apt``, ``yum``)

Command-Line Tools (``cp``, ``grep``, ``ping``, etc)

Graphical User Interface (GUI)
(LibreOffice, Control Center, Thunderbird)

File System

Definition: Hierarchical structure of the linux file system

Description of important directories and their purposes:

- /bin: Essential system binaries.
- /etc: System configuration files.
- /home: User home directories.
- /usr: User-related programs and data.
- /var: Variable files (e.g., log files, mail).
- /tmp: Temporary files.
- /dev: Device files.
- /proc: Virtual file system providing process and system information.

Graphical User Interface (GUI)

Definition: Provides a visual way to interact with the operating system

Components:

- Window manager
- Panel
- Desktop icons
- File Manager
- Settings Manager

Hardware Layer

Linux Operating system contains a hardware layer that consists of several peripherals like CPU, HDD, RAM
